The existing facility was constructed in 1959 with an addition in 1974 and another in 1995. The central boiler system dates to the original construction. It was altered somewhat in the 1995 addition. It continues to supply hot water to the Chapel and Cultural Center air handlers as well as the perimeter fin pipe heating system installed at nearly all perimeter rooms. While the boiler and associated piping appear to be in good condition they are well beyond the listed ASHRAE life cycle of 25 years. There were some reports of leaking pipes but I believe much of that can be attributed to a single issue. The risers from pipes located in the tunnel travel through the floor. It appears the thermal expansion difference of the fin pipe units to the piping below eventually fatigued the riser pipe. The resulting leak is mostly an isolated case and does not necessarily indicate that the heating water piping is universally in poor condition.

The focus of this report is to develop options for adding cooling to those spaces in the facility currently without. Attached is a highlighted floor plan from the 1995 addition and remodel.

Area 1 (Chapel) is served by a central air handler in the mechanical mezzanine. This unit was modified with the addition of direct expansion (DX) refrigerant coils in 1995. The condensing units should be considered on borrowed time as any compressor unit older than 20 years has the potential to need more service then the value of the unit. However, replacement will involve the replacement of the interior coil as well as the outdoor unit because of the switch from R-22 to R-410A. Replacing the indoor coils due to location will not be an easy task. As noted before heat for this area is from the central boiler to a hot water coil. There is an airside economizer on this system. Control of the system is via older Honeywell electric controls installed in 1995.

Area 2 (Cultural Center) is served by a central air handler in the mechanical mezzanine. This unit was modified with the addition of direct expansion (DX) refrigerant coils in 1995. The same as noted for the Chapel unit can be said of the cooling system for this area.

Area 3 (West Office Areas) is cooled with ductless mini-split units installed in 1995. These are units that have a wall mounted indoor unit connected to a small outdoor unit with copper refrigerant lines. These units carry the same concerns as the other 20 year old compressor equipped systems. Replacement when either the interior or exterior unit fails would involve complete replacement of indoor and outdoor units. However, due to the devices location and size replacement is not difficult. Heat is provided as noted earlier from perimeter hot water fin pipe units. Controls are from 1995 and are either thermostatically controlled direct acting electric valves or self-contained thermostatically controlled valves. Mechanical ventilation for this area is non-existent. Operable windows serve the ventilation needs but appear to be undersized based on current code.

Area 4 (North Classroom Areas) is cooled with ductless mini-split units installed prior to 1995. The area these units serve is somewhat flexible. In both 4A and 4B areas there are two units serving three rooms if the folding partitions are open. If the partitions are closed the center two classrooms receive no cooling. At the time of the visit the folding partitions were open. The commentary

associated with the Area 3 systems (relative to ventilation, heating, and cooling) would apply to these systems as well.

**Area 5 (Relief Society)** is cooled with a furnace and DX coil located in one of the nearby storage rooms. The gas furnace is ducted to floor supply grilles. This system is very similar to those used at many of the Meeting Houses in this region. There is an R-22 condensing unit that predates the 1995 work serving this system. Ventilation is provided by a duct from the return side of the unit to the exterior.

**Area 6 (South Office Areas)** is cooled with ductless mini-split units installed in 1995. See commentary related to Area 3 for more information.

The balance of the areas are heated with hot water fin pipe units served by the central boiler. The exception to this are the two classrooms east of the women's restrooms (Room 121 and 122). Those rooms have hot water fed fan coil units for heat (FC-1 and 2). Ventilation to these spaces is provided by ductwork routed to the exterior sized for a full economizer cycle. Controls to all these systems were installed in 1995.

It is important to note that the current electrical service is a 240v Delta three phase system. The entire service is rated at 600-Amps but the three phase portion of that system is limited to 400-Amps. We don't have an electric demand for this facility. Based on other Stake buildings with 600-Amp services the service has sufficient capacity to add more load. We would estimate the current service peak demand is about 210-Amps. The Delta service is a concern as it relates to the service transformer. If sufficient load is added that requires an up-sizing of the transformer the serving utility may not support the Delta service. If that is the case there may be a charge from the utility to change the transformers. The conductors are sized sufficiently for the 600-Amp load. A change to a Y-service from the Delta would require a relabeling of the service at the least. Potentially the main switch board (dating to 1958) would need to be replaced. If the service were replaced any 240 volt loads would need to be converted to 208 volt compatible devices. This could affect existing condensing units and motors in the air handling units that serve the Chapel and Cultural Center.

#### **Cooling Option #1**

Retain the existing DX systems noted in areas 1, 2, 3, 4, 5, and 6. Maintain those systems per current methods and replace when failures occur. Confirm boiler water treatment is monitored and administered correctly.

Rooms 121 and 122: Due to the small size of FC-1 and FC-2 adding DX coils to these units will be difficult. Matching outdoor units to these types of coils is impossible with today's offerings. For that reason I suggest adding ductless mini-splits to each room. Similar to the current spaces cooled with mini-split units there will be a wall mounted fan-coil unit with an outdoor ground mounted condensing unit for each system. Provide controls to eliminate the possibility of simultaneous heating and cooling. Please note that ductless mini-split systems are not currently listed in the LDS Construction Specifications Standards but have been used successfully on several recent LDS buildings.

**Rooms 112, 114, 155 and 162:** Add a ductless mini-split to each room. System configuration information is per above. At the Serving 155 I suggest a heat-pump unit since there is an absence of hydronic heat in this room currently.

Rooms 126 to 130 and 134: Install a gas fired condensing furnace in a portion of the storage room at the east side of the facility. Gas furnace system to include DX coil and exterior ground mounted condensing unit. Duct ceiling supply air in the attic space and floor returns to the crawl space. Due to the slab on grade construction the return air for room 134 will need to be ducted overhead. Provide with Honeywell Jade controller (per LDS control standards). Eliminate fin pipe units from this area or provide controls to allow those devices to supplement gas heating portion of the furnace system only during heating operation. The size of this system is large enough so as to anticipate the need or reasonable desire for an air-side economizer rather than just a minimum outside air source. These new system elements are per LDS Construction Specifications Standards.

Rooms 101 to 103 and 107 to 109: Install two gas-fired condensing furnaces in a portion of the mechanical / boiler room. Duct both supply air and return air in the attic space as the construction of this area is slab on grade. One furnace is to cover the east facing rooms while the second is to cover the west. This will provide sub-zoning based on exposure. Provide with Honeywell Jade controller (per LDS control standards). Eliminate fin pipe units from this area or provide controls to allow those devices to supplement gas heating portion of the furnace system only during heating operation. Each system is small enough that neither code nor practical design would require an air-side economizer. Only a ventilation duct to the exterior is required. These new system elements are per LDS Construction Specifications Standards.

### **Option #1 Benefits**

This option would be the least costly of the options suggested.

Systems are relatively easy to maintain, controls were necessary are per LDS standards.

The heating system at the exterior perimeter offices and classrooms is fin-pipe. This type of is a very comfortable heat.

#### Option #1 Draw-Backs

This option does not provide for any cooling in the foyers, vestibules, restrooms or corridors of the facility.

The 20 year old existing cooling systems are not replaced. Or at least don't have to be replaced.

The 1958 heating system is not replaced. These components could be replaced but that will increase this options cost.

Lack of ventilation air in some spaces that retain mini-split systems do not have ventilation air.

Number of compressors matched the number of zones.

### **Cooling Option #2**

This option is called Variable Refrigerant Flow (VRF). This system allows multiple indoor units to be connected to a single outdoor condensing unit style heat pump. These systems are very efficient. They use EC motor fans in the fan-coil units. So they use only as much power as necessary to move the required air to maintain the necessary temperature across the heating / cooling coil. This varies with load. They use invertor driven compressor motors and so have modulating capacity for heating / cooling rather than staged compressors or hot gas by-pass. They include a controller that allows heat from one zone that is in cooling mode to be used in another zone that needs heat. By intentionally mixing exposes on the same compressor unit maximum heat recovery potential is achieved. There are many indoor unit options. The basic components of the system are a single outdoor heat pump compressor unit for a given number of indoor fan-coil units. Each fan-coil unit is piped to the outdoor unit through a heat recovery control unit. The piping that connects these components is copper refrigerant piping operating at pressures of about 450 PSI on the high side of the cycle. By using refrigerant piping to transfer energy to the zones these systems are ideal for remodel and retrofit installations as refrigerant piping is smaller than ductwork or water piping. Zoning could be more extensive than Option #1 if wall mounted or cassette units are used. If ducted fan coils are used the zoning of the Option #1 could be matched. For spaces such as offices that have a low occupancy level I would suggest using a cassette or ducted unit so that ventilation air can be connected to the system directly. At the large high occupancy spaces I would suggest using air handler kits that would allow connection of the VRF outdoor compressors to those units. The air handlers would receive new refrigerant coils designed for operation with R-410a refrigerant (replacing those installed in 1995). In those spaces with higher occupancies (such as classrooms) I would recommend the installation of a ventilation recovery (heat recovery) unit. Cut sheets include an example of this type of unit. Ventilation air in quantities to satisfy the Mechanical code are brought in from outside. That air crosses an energy recovery cell that has the exhaust air stream on the other side. Through this energy recovery cell the warm or cool energy from the room exhaust provides a pre-heat or pre-cool function to the ventilation air. This heat recover system is not required for smaller zones but it is a nice way of somewhat controlling the temperature of ventilation air brought into the zones outside of the VRF fan-coil unit.

#### **Option #2 Benefits**

All new refrigerant piping takes the place of the existing heating water piping

New outdoor heat pump takes the place of the boiler and provides cooling at all zones

Package control system can be relatively easy to use depending on interface purchased.

Very quiet operating system

Highest efficiency of the three systems

Can be designed to include more zones then Option # 1.

#### **Option #2 Draw-Backs**

More costly then Option #1. For the purposes of comparison the zoning of Option #1 was used in the schematic estimate for Option #2. Additionally the means of ventilation is matched between the two systems; meaning if the space currently uses windows for ventilation under Option #1 that remains the same under Option #2. This will need to be confirmed code compliant if this option is selected.

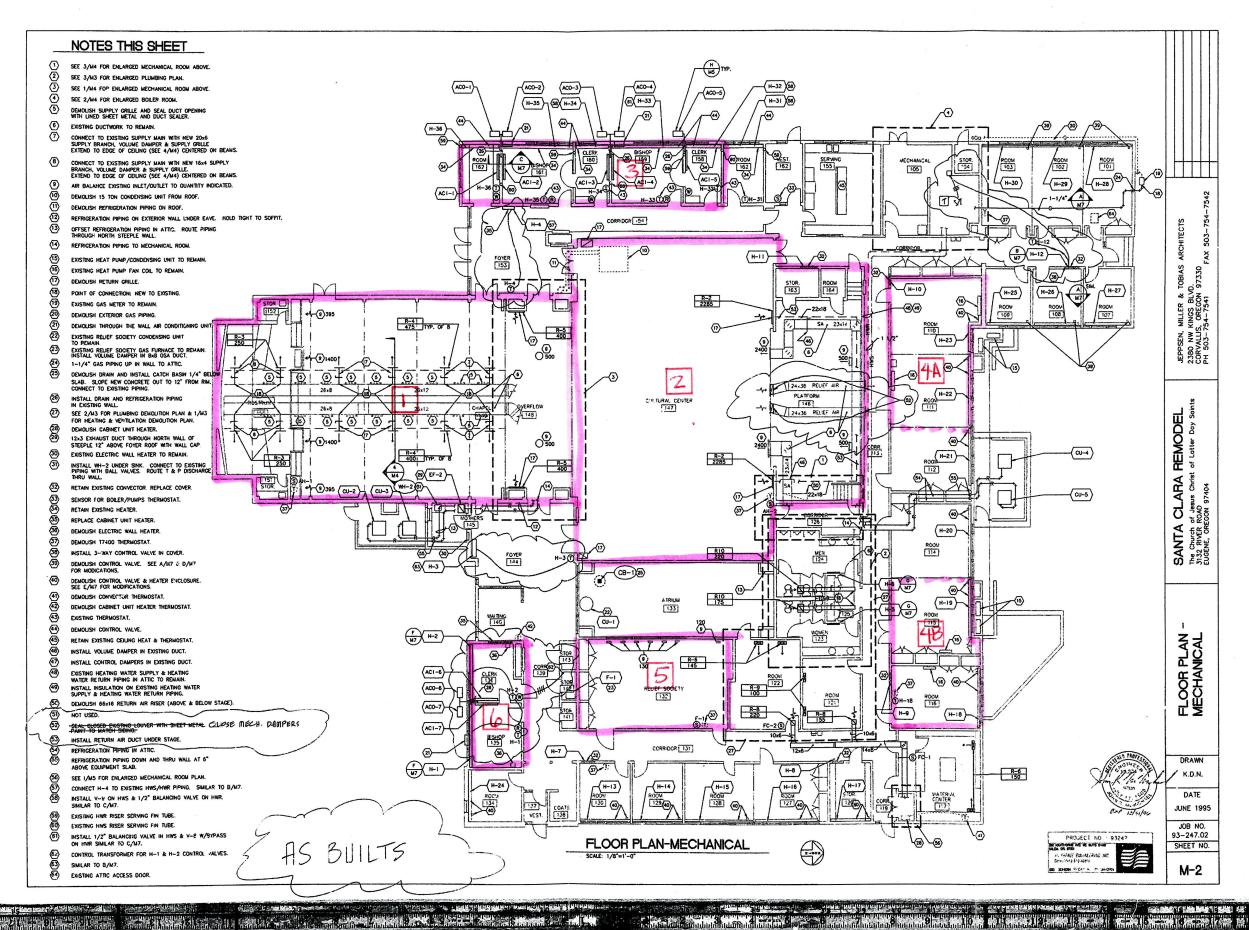

System and control components do not meet LDS Standards

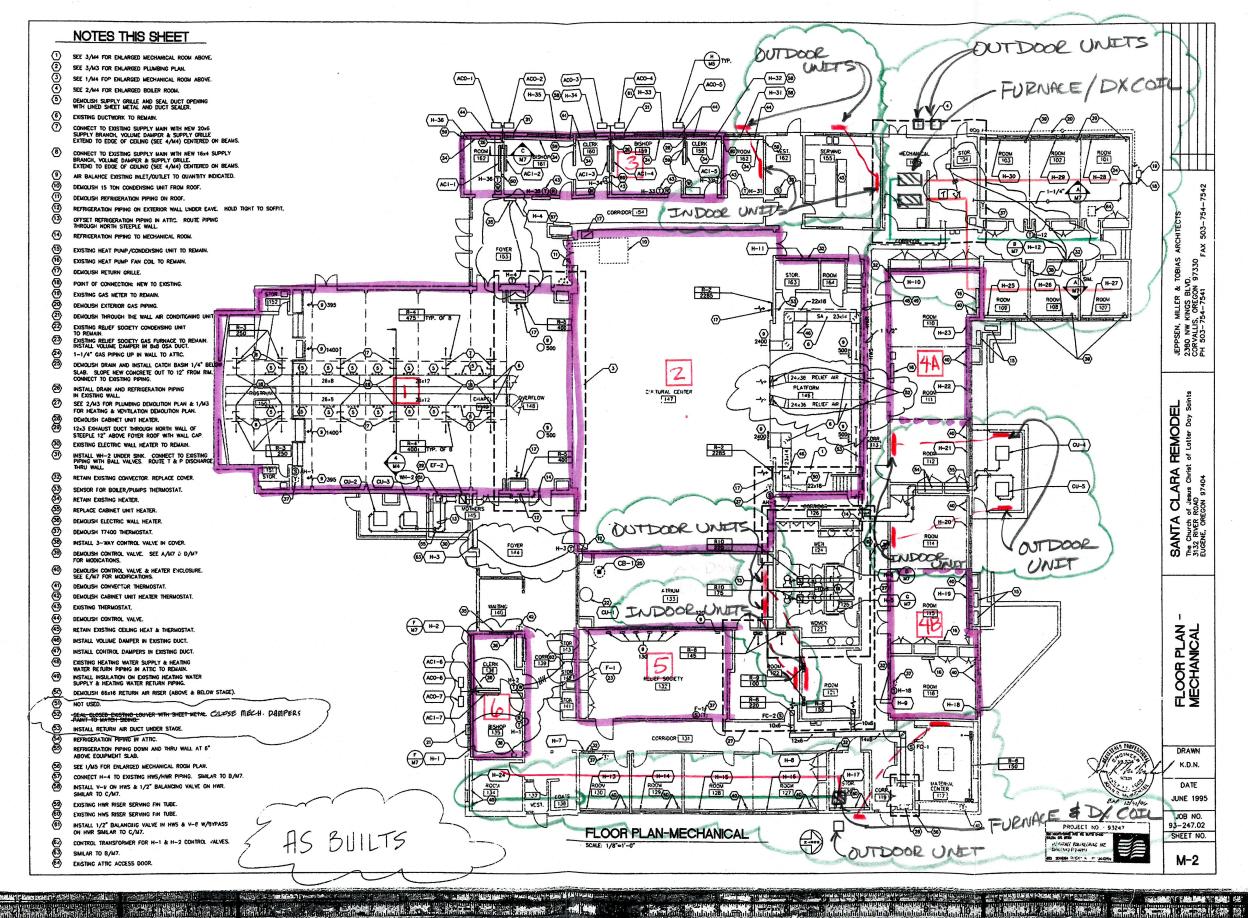

Ventilation of space with operable windows could remain without mechanical ventilation

#### INDOOR UNIT

#### **SPECIFICATIONS**

#### **Ventilation Type:**

Static plate, heat and humidity transfer

Typical Airflow Range: 375-1,575 CFM

#### **AHRI 1060 Certified Core:**

One L62-G5 and one L125-G5

#### **Standard Features:**

Non-fused disconnect 24 VAC transformer/relay package

Total gty. 4, MERV 8: (2) 14" x 20" x 2" and (2) 16" x 20" x 2"

#### **Unit Dimensions & Weight:**

53 1/4" L x 34 1/2" W x 53 3/4" H 336-463 lbs.

#### Max. Shipping Dimensions & Weight (on pallet): 70" L x 47" W x 53" H
